

HP Z820 Workstation + Mac OS X Yosemite/El Capitan

Beitrag von „drdude“ vom 19. Juni 2016, 07:25

Hi all, I hope you don't mind a lowly z620 user joining the conversation 😊 First off, ibnahmed, thanks for sharing your clover folder, I wanted to try OS X on the z620 but could not get it to install at all, due to USB issues (very hard for a first time hackintosh builder...). Was about to give up, used your clover folder, and almost everything worked like a charm! One million times thanks!

But, forum posts should also be about giving back, so here is two things that did not work for me initially, and do work now, and may work for you:

- memory: the z620 has 12 banks, only 8 were showing. I used clover configurator to define memory in the SMBIOS. Started slowly by defining only one bank, rebooting, and that worked, gradually added all (I used a text editor on config.plist after the first one). I defined quad channel and also the proper SlotCount. This does not affect DSDT, only config.plist (I believe). Nice side effect is that I now get to define the memory as DDR3-1600, not 1333 as it was at first.

- audio: the onboard audio (probably ALC262) works with the patched VoodooHDA 2.87 [sic] found here: <http://www.insanelymac.com/forum/...-1010x1011x-installation/>
