When you were using your dedicated GPU, did you disable your iGPU in your BIOS?

[@taoarch](#) I know of this problem but as far as I am concerned it's only present when both iGPU and ded. GPU are used. Normally the MojaveBoot should work when only one GPU is activated, so it should work too, when only the HD4000/HD4600 is present...

The whole issue is very weird because the error appears so early in the boot process that I don't think that any driver or AGDP could possibly be responsible for that. Also I really don't understand why Clover users don't face this issue. There has to be some patch that Clover automatically applies, that Ozmosis doesn't perform (maybe MSR or Lapic but I tested that and that wasn't the issue).
Also I experienced that issue too but very inconsistently. Sometimes the PC would just work as normal with both GPUs and one restart later the Ozmosis Logo would freeze, no verbose output (too early in the boot process?)
I don't know if this could have anything to do with Ozmosis internal AptioFix or similar. I don't know if there's a difference for AptioFix (or the problematic memory-sections) if the iGPU is activated or not. Maybe [@Download-Fritz](#) could help us with that. 🙁 The fact though, that the issue is that inconsistent, let's me think that it could be AF related...
