No, you shouldn't use the iMac18,3 at all. It requires using Quick Sync and with Quick Sync enabled mostly your IGPU is used for video acceleration. Obviously your IGPU is slower than your Vega which means you are missing out on performance.

The iMacPro1,1 SMBIOS is made for use with the Vega cards and no IGPU so your Vega will be fully utilized. No need for NoVPAJpeg.kext either. NoVPAJpeg.kext is only needed if the SMBIOS used doesn't match the graphics hardware.
