U

OZ

OZ BIOS

U

MacOS

After the BIOS of Oz is finished, the installation method is the same as that of Macintosh . First, you need to have an apple system environment, and then, from the app Store downloads the system installation package, prepares a U disk of about 8g, and then makes the Mac OS installation disk with the command in the terminal (the installation disk made in this way can also be used by Macintosh). Then the computer plugs in the U disk, and after power on, oz will guide the MAC OS installer on the U disk to install the system. If you have all the drivers in your BIOS, you can install them successfully. If it gets stuck halfway, you need to open the EFI partition of the USB flash drive with the existing Apple system, and add the missing drivers, such as whatevergreen and Lilu. After the installation is completed, these drivers can also be added to the BIOS. In this way, if you install later, you can change any hard disk without restrictions, and you don't need to add any files to the EFI partition. Oz is not perfect. It is recommended to integrate the driver into BIOS and boot with oz after the clover is perfect. Clover first, oz later.

Something else happened these two days, so I didn't reply in time. I'm sorry.
