TINU doesn't just copy your installer app on the usb drive, it performs a more complex process which includes checks, formats and the creation of several invisible files on the usb driver to allow booting the macOS installer out of it.

Most of this stuff is perfomed by the createinstallmedia executable which is an offial apple program for teh terminal made for installer creation, tinu manages it and perorms checks to make sure it will succeed in doing it's job.

About questions you can also ask me since i am the developer of tinu, but i can answer just in english.

I have also to say that just installing clover will not let you boot into macOS, clover should be configured according to your hw configuration, this incluses using the proper clover drivers, the proper kexts and and configuring the clover's config.plist with the right settings. all of this clover stuff is performed (badly) when using unibeast by the tool, but i left it to the user for tinu because for a proper hackintosh all of this stuff should be done specifially for each machine
