The BIOS Version you are running (2103) is fine. It is the same as mine.

As I understand you are now trying to install High Sierra and it stops installing at around 40% of the installation?

I have looked at your config.plist and it looks fine to me. Maybe in "Kernel -> Quirks -> AppleXcpmCfgLock" you could it set to "false"

because I think on this Motherboard it is possible to disable CFG Lock in the BIOS. But I can't check it at the moment because I have

no access to this PC.

But it could also be enabled. It shouldn't have to do something with the Install Process. The Rest of the config.plist looks good to me.

From the log file I can't read very much information because I don't know what the information means xD.

Your Hardware looks fine and I think you should be able to install High Sierra with this config.plist.

Maybe there is a Problem specific with the Intel SSD but I really don't know if this is even a problem.

Maybe you could try to unplug everything from the PC (other Hard Drives, Optical Drives, Expansion Cards like USB3.0 and so on)

and just try to install with the only display, mouse and keyboard and network connected.

If it doesn't work you should open a seperate Thread. I am no expert so I have no Ideas why it stops at around 40%.
