Wo genau ist meine Frage richtig: Update von 10.13.6 auf 10.15.7 läuft nicht sauber, vielleicht gleich auf Montery?

I mean your previous and working EFI with HighSierra OS was weird

Inside some stuff of Nvidia and others weird thing

You say it does not start anymore also your High Sierra disk if I am not wrong

Now I have converted and updated your previous EFi

If you can rebuild the same situation of your previous bios configuration settings this EFI could boot system from HighSierra to Monterey

I doubt because I do not see a mandatory SSDT for your motherboard Chipset

But, if it was working previously it must work also now 🙂

EDIT use this config because inside EFI I have used patches for 12cores CPU (sorry)
